(54) Torsion isolator spring with pivotal ends.

(57) A torsion isolator (34) for transmitting torque and dampening torsionals in a driveline. The isolator includes a composite c-shaped spring (48) disposed in an annular chamber (44) of a housing (38,40) filled with torque converter fluid. The spring transmits driveline torque and attenuates torsionals. The spring also functions as a fluid displacement piston by dividing the chamber into radially inner and outer volumes (44a,44b) which vary inversely in volume in response to torque changes flexing the spring. Rapid flexing of the spring increases the fluid pressure in the decreasing volume and thereby dampens or reduces the rate of spring flexing or rebound.

FIG 2

EP 0 682 194 A1

Field of the Invention

This invention relates to torsion isolator. More specifically, the invention relates to an isolator for attenuating and dampening vehicle driveline torsional.

Background of the Invention

It is well known that the speed of an Otto or Diesel cycle engine output or crankshaft varies even during so-called steady-state operation of the engine, i.e., the shaft continuously accelerates and decelerates about the average speed of the shaft. The accelerations and decelerations are, of course for the most part, a result of power pulses from the engine cylinders. The pulses may be of uniform frequency and amplitude when cylinder charge density, air/fuel ratio and ignition are uniform. However, such uniformity does not always occur, thereby producing pulses which vary substantially in frequency and amplitude. Whether uniform or not, the pulses, which are herein referred to as torsionals, are transmitted through vehicle drivelines and are perceptible to vehicle passengers. The torsionals, which manifest themselves as vibrations are detrimental to drivelines, derogate passenger-ride quality, and may cause annoying body noises. An example of body noise, known as body boom, occurs when an engine is lugged; under such a condition engine torsionals may cause body components, such as sheet metal panels, to resonate. Still further, tip-in/tip-out torque pulses, produced by abrupt engine acceleration and/or deceleration, jerk the driveline and vehicle; such torque pulses are also referred to herein as torsionals.

Torsion isolators for attenuating and dampening driveline torsionals are well known in the prior art. Such isolators commonly employ a spring(s) and a damper. The spring(s) attenuate the torsionals and transmit positive and negative torque (i.e., engine and coast torque) between the vehicle engine and wheels. The damper controls the rate of spring flexing. Examples of such isolators may be seen by reference to U.S. Patents 5,240,457; 5,234,377; 4,782,932 and published French patent application 2,611,013. These documents are incorporated herein by reference. The torsion isolator disclosed herein is considered to have several advantages over the above torsion isolators with respect to torsional attenuation and damping, cost, and weight or inertia.

Summary of the Invention

An object of the invention is to provide an improved torsion isolator.

According to a feature of this invention, a torsion isolator, such as disclosed in U.S. Patent 5,234,377, includes first and second drives mounted for relative rotation about a common axis. A c-shaped spring has a flexible major arc portion circumscribing the axis and has first and second circumferentially spaced apart ends. Attachment means conned the first and second ends respectively to the first and second drives at a radial distance from the axis. The spring transmits torque between the drives and attenuates torsionals. The spring ends are circumferentially movable relative to each other in response to changing values of the torque and torsionals.

The improvement is characterized by the spring first and second ends respectively including first and second brackets rigidly affixed thereto. Pivot means pivotally connect the first and second brackets respectively to the first and second drives. Stop means are operative in response to a predetermined amount of pivotal movement of the brackets to stop further pivotal movement.

Brief Description of The Drawings

The torsion isolator of the present invention is shown in the accompanying drawings in which:

Figure 1 is a schematic view of a motor vehicle driveline;

Figure 2 is a detailed, sectional view of the torsion isolator disposed in a partially shown torque converter housing and looking along line 2-2 of Figure 3;

Figure 3 is a relief view of the torsion isolator of Figure 2 with a housing member removed and looking in the direction of arrow 3 in Figure 2;

Figure 4 is a sectional view of the torsion isolator looking along line 4-4 of Figure 3;

Figure 5 is a relief view similar to Figure 3 with a spring therein shown fully stressed in one direction;

Figure 6 is an exploded view of the torsion isolator;

Figure 7 is a sectioned half view of a second embodiment of the torsion isolator;

Figure 8 is an enlarged schematic view of a portion of a composite spring illustrating layers of reinforcing filaments protruding from a matrix of plastic material;

Figures 9-11 illustrate an active counterbalance mechanism for the torsion isolator of Figures 2-6;

Figures 12 and 13 illustrate slack mechanism for the isolator of Figures 2-6; and

Figure 14 illustrates an alternative slack mechanism embodiment.

Detailed Description of The Drawings

The motor vehicle driveline seen schematically in Figure 1 includes an internal combustion engine 10, an automatic transmission 12 and a drive shaft 14 driving a load such as rear and/or front wheels 16 of a vehicle through a differential 18.

The transmission includes a torque converter assembly 20 having an output shaft 22 rotatable about an axis 22a (Figure 2) and a gear ratio box 24 driven by the torque converter output shaft 22. Torque converter assembly 20 is filled with automatic transmission fluid and includes, in a known manner, an impeller 26 driven by engine 10 through a torque converter housing 28, a stator 30, and a turbine 32 driven hydrokinetically by the impeller. A fluid coupling may be employed in lieu of a torque converter.

Torque converter assembly 20 further includes the torsion isolator 34 of the present invention disposed to selectively bypass the torque converter impeller in response to pressurized torque converter fluid hydraulically moving the torsion isolator axially into frictional engagement with the torque converter housing 28 by a friction material 35 in known manner. During non-bypass operation of the torque converter, the pressurized torque converter fluid is admitted to the torque converter via a chamber 36 receiving the fluid through unshown passages in shaft 22 in known manner. The fluid in chamber 36 prevents frictional engagement of the isolator housing with the torque converter housing. The fluid in chamber 36 flows radially outward and into the torque converter in a main torque converter chamber 37 separated from chamber 36 by isolator 34. When it is desired to engage the isolator, as for example, when the vehicle is in motion, the direction of flow of the pressurized fluid is reversed by actuation of a suitable valve, not shown. Specifically, the pressurized fluid is now admitted to chamber 37 where it acts against the radially extending portion of the isolator facing chamber 37 and slides the entire isolator to the right to effect frictional engagement with the torque converter housing. Driveline torque now bypasses the torque converter and is transmitted to shaft 22 by the isolator.

Referring now to Figures 2-6, torsion isolator 34 comprises housing members 38,40 and an annular ring 42 defining an annular chamber 44, a hub 46, and a c-shaped spring 48. Housing member 38 includes a radially extending portion 38a having a surface 38b defining an axially facing surface of chamber 44, a radially outer and axially extending portion 38c having a cylindrical surface 38d defining a radially outer surface of the chamber, and a radially inner and axially extending portion 38e concentric to axis 22a when mounted for

relative sliding and rotational movement on an end of shaft 22. Oil leakage flow between the interface of shaft 22 and housing portion 38e is prevented by an o-ring seal 50.

Hub 46 includes a radially inner and axially extending portion 46a rotatably supported on housing portion 38e by a needle bearing 52, a plurality of circumferentially spaced apart holes 46b slidably receiving extensions of fasteners 53 drivingly securing turbine 32 to shaft 22, axially oppositely facing annular surfaces 46c,46d, and an arm 46e extending radially outward from annular surfaces 46c,46d and into annular chamber 44. Surface 46d is disposed for sliding sealing relation with a radially inner portion of housing surface 38b.

Annular ring 42 includes an arcuate opening or recess 42a having hub arm 46e extending therethrough, end surfaces 42b,42c defining the arcuate length of the recess, an axially facing annular surface 42d disposed for sliding sealing relation with hub surface 46c, an inner circumference 42e concentric to hub portion 46a, an elliptical or irregular outer circumferential surface 42f explained further hereinafter, axially spaced apart surfaces 42g,42h, an annular shoulder or ridge 42i, and three substantially equally spaced apart recesses 42j in shoulder 42i.

C-shaped spring 48 is preferably, but not necessarily formed of a composite material including layers of reinforcing filaments 47 encapsulated in a matrix of plastic material 49 in known manner. See Figure 8. Further details of such springs may be obtained by reference to U.S. Patents 5,219,431 and 5,234,377, which are incorporated herein by reference, or from A. O. Smith Corporation, Milwaukee, Wisconsin, U.S.A. Spring 48 includes circumferentially spaced apart and aligned ends 48a,48b and a bracket 54 affixed to each end. The brackets may be affixed to the spring ends in any of several known manners. Herein screws 56 are used. A radially inner portion of each bracket has an axial thickness less than the axial thickness of spring 48 and a slot 54a. The bracket affixed to spring end 48a loosely receives hub arm 46e in slot 54a with axial free play and is pivotally connected thereto by a pin 58 extending through openings in the bracket and arm. The bracket affixed to spring end 48b is pivotally connected to housing members 38,40 by a pin 60 extending through openings in the bracket and housing members. The bracket affixed to spring end 48b need not include slot 54a. A radially outer portion of each bracket has axially oppositely facing surfaces 54b,54c flush with axially oppositely facing surfaces 48c,48d of spring 48, a radially outwardly facing surface 54d having a radius of curvature complementary to and in sliding sealing relation with housing member surface 38d, and an edge 54e of each surface 54d has a re-

duced radius concentric to pins 58,60 so as to allow pivotal movement of the brackets and maintain the sliding sealing relation with the housing surface 38d.

Radial positioning of housing member 40 relative to housing member 38 and annular ring 42 is provided by outer and inner circumferential surfaces 40a,40b of housing member 40, which are snugly received respectively by housing surface 38d and ring annular shoulder 42i. Axial positioning of an axially facing surface 40c of housing member 40 relative to housing surface 38b to provide desired clearance with spring surfaces 48c,48d may be determined solely by dimensional control of the distance between annular ring surfaces 42g,42h relative to the distance between spring surfaces 48c,48d. Alternatively, the cost of dimensional control may be mitigated by positioning radially extending assembly shims (not shown) between surfaces 40c,48c of the housing and spring. The shims may be inserted through annular ring recesses 42j and removed after housing outer circumferential surface 40a is sealingly affixed, for example by welding, to housing surface 38d. Thereafter housing member 40 is affixed at a radially inner portion thereof to annular ring 42 and housing member 38 by fasteners such as rivets 62.

Isolator 34, when installed, is intended to rotate in one direction as indicated by arrow A in Figures 3 and 5. Direction A is taken as the direction of positive torque, i.e., when torque is from the engine to the wheels. Torque in the opposite direction is taken as negative or coast mode torque which is produced when drive is from the wheels to the engine. Positive torque moves the spring ends circumferentially toward each other and decreases the spring radius. Negative torque moves the spring ends circumferentially apart and increases the spring radius. Maximum flex of spring 48 in the positive and negative directions from the neutral or unflexed position of Figure 3 may be limited to any of several predetermined amounts. Herein, maximum flex in the positive torque direction is limited to about forty-five rotational degrees by contact of bracket end surfaces or stops 54f, as seen in Figure 5. Maximum flex in the negative torque direction is limited to about fifteen degrees. Flex in the negative torque direction may be limited in any of several ways, for example, by hub arm 46e contact with annular ring recess end surface 42c, by contact of the spring outer circumference with housing surface 38d, etc.

The rate of spring 48 may be varied by allowing brackets 54 to pivot or not pivot about pins 58,60 while the spring is flexing. When a relatively low rate is desired, for example, when driving torque is low, pivotal movement may be allowed and then prevented at some higher torque. Herein,

by way of example, brackets 54 are allowed to pivot during the first ten degrees of spring flexing in the positive direction from the neutral position. Pivotal movement of the bracket affixed to spring end 48a is arrested or stopped when a bracket surface 54g contacts a surface 46f of hub arm 46e. Pivotal movement of the bracket affixed to spring end 48b is arrested or stopped when bracket surface 54g contacts the outer surface 42e of annular ring 42.

The flexing of spring 48, as thus far described, has had to do only with respect to torque transmission and torsional attenuation functions of the spring. Spring 48 also functions as a fluid displacement piston by dividing chamber 44 into radially inner and outer volumes 44a,44b which vary inversely in volume in response to torque changes flexing the spring. The volumes are filled with torque converter fluid, are in restricted fluid communication with each other by the sealing relation between the spring and bracket surfaces and the housing surfaces, and are in restricted fluid communication with the surrounding pressurized fluid in the torque converter by the less than tight sealing relation between surfaces 38b,46d and 46c,42d to ensure full charge of the volumes. Rapid flexing of the spring increases the fluid pressure in the decreasing volume and thereby dampens or reduces the rate of spring flexing or rebound. Accordingly, housing 38,40, hub 46, spring 48 and the fluid define a fluid dampening mechanism. As may be seen by reference to Figure 5, the elliptical or irregular surface 42e of annular ring is to allow full positive flexing of spring 48 without contact of the spring central portion 48e therewith.

The torsion isolator, as thus far described, is charged by and refilled by the pressurized fluid in the torque converter housing. Alternatively, the isolator may be better sealed as in partially shown torsion isolator 70 in Figure 7. Isolator 70 has a modified, two piece annular ring 72,74 and hub 76 to accommodate dynamic seals 78,80. The fluid within the isolator may be other than torque converter fluid, for example, silicone oil. Further, isolator 70 may be employed in a free standing master clutch plate commonly used in non-torque converter transmissions or as an inline isolator in any type of driveline. Still further, edges of spring 48 and brackets 54 may be provided with chambers or bevels 48f to promote generation of a hydrodynamic fluid film between spring and bracket surfaces 48c,48d,54b,54c and housing surfaces 38b,40c for reducing friction and wear therebetween.

Rotational balance of isolator 34 is subject to change since concentricity of spring 48 relative to shaft axis 22a changes as it flexes. The changing balance may be cancelled by use of, for example,

two or more springs disposed in separate chambers and circumferentially positioned about axis 22a such that the collective balance of the springs does not change as they flex. Herein, the change in balance is a relatively small amount since the spring is disposed in a closed chamber filled with a fluid whose density is relatively close to the density of the composite material of the spring. However, the change in balance would be greater if the spring were formed of a denser material such as steel, or if a single spring 48 were used in lieu of the spiral springs in U.S. Patent 5,240,457, on in combination with the viscous fluid damper in U.S. Patent 4,936,434 incorporated herein by reference.

Isolator 34 may also include some type of dynamic or active counterbalance mechanism to counter out of balance conditions caused by flexing of spring 48. Herein, brackets 54 function as active counterbalance mechanisms since they pivot radially inward in response to positive flexing of the spring from the neutral position of Figure 3 to the fully flexed position of Figure 5.

Figures 9-11 illustrate a torsion isolator 90 modified to include an active counterbalance mechanism 92 which may be used in lieu of or in addition to the counterbalance provided by pivoting spring brackets 54. Mechanism 92 includes a counterweight 94 disposed for radial movement in an elongated window 96a of a modified hub 96 in response to flexing of spring 48 allowing rotational movement of the hub relative to a ring 98 affixed to a housing member 100 in a manner analogous to the way rings 42 and 74 are affixed. Transmission of the radial movement is effected by a follower 94a of the weight projecting into a cam slot 98a in ring 98. As spring 48 flexes in the positive direction, slot 98a pulls weight 94 radially inward. As spring 48 flexes in the negative direction, the slot allows the weight to move radially outward. Mechanism 90 or an equivalent thereof may be disposed in any of several places in or on the torsional isolator. For example, mechanism 90 may be disposed diametrically opposite the shown position provided cam slot 98a is positioned to move the weight radially outward in response to increasing positive flex of the spring and radially inward in response to increasing negative flex. Further, cam slot 98a may have a curved profile in lieu of the linear profile shown so as to provide nonlinear movement of the weight in response to spring flex.

Isolator 34 may also be provided with a lost dampening mechanism for reducing or negating dampening of low amplitude torsionals since the effects of such torsionals are readily attenuated or masked by a long travel spring such as spring 48 without dissipation of the torsional energy by the damper. By way of example, the lost dampening mechanism may have an operative range of one or

two rotational degrees on either side of a current steady state or average torque. The lost dampening may be provided by a lost motion mechanism such as disclosed in U.S. Patent 4,608,883, which is incorporated herein by reference. However, the mechanism is preferably a hydraulic slack mechanism, two of such mechanisms are disclosed herein.

Referring now to Figures 12 and 13, therein is illustrated a first hydraulic slack mechanism 110 for allowing momentary flow of torque converter fluid from one of the radially inner or outer volumes 44a,44b to the other and thereby slow or delay pressure rise in one volume and fall in the other in response to torsionals as they tend to decrease the size of one volume and increase the size of the other volume. The amount of fluid flow allowed by mechanism 110, of course, determines the amount of slack or non-hydraulic dampening of spring flexing.

Mechanism 110 is incorporated into a spring bracket 112 which is otherwise the same as bracket 54 and which replaces one or both of brackets 54 in isolator 34. Mechanism 110 includes a circumferentially extending groove 114 formed in the radially outer surface 112a of the bracket and a circumferentially movable valving member 116 disposed in the groove. Groove 114 includes a groove portion 114a circumferentially bounded at its opposite ends by shoulders 114b,114c formed by radially deeper groove portions 114d,114e. The valving member includes, relative to axis 22a, axially oppositely facing sides 116a,116b in close sliding relation to the axially facing sides of the groove, a circumferentially extending portion 116c having radially inwardly extending ends 116d,116e respectively received by groove portions 114d,114e and movable into sealing relation with shoulders 114b,114c. When valving member ends 116d,116e are spaced from shoulder 114b,114c, torque converter fluid can flow between the volumes 44a,44b. As pressure rises in one volume and falls in the other, the differential pressure created thereby acts on valving member ends 116d,116e and shuttles the valving member away from the rising pressure and seals the appropriate ends 116d,116e against the corresponding shoulders 114b,114c. The amount of fluid that flows during the shuttle period determines the slack or non-hydraulic dampening of the spring flex.

To provide the desired amount of slack or non-dampening in some applications, a low force spring or springs, not shown, may be employed to position valving member 116 in the neutral position shown, thereby increasing the amount of differential pressure for shuttling the valving member. Further, if or when both of the spring brackets are provided with valving member 116, one of the

valving members may be biased by an unshown low force spring toward shoulder 114b thereby preventing flow from volume 44b to volume 44a and the other biased by an unshown low force spring toward shoulder 114c thereby preventing flow from volume 44a to volume 44b. This arrangement is believed to provide more precise valve control.

Referring now to Figure 14, therein is illustrated a lower half of isolator 34 having a pair of second hydraulic slack mechanisms 120, 122 for respectively allowing momentarily expansion of volumes 44a, 44b as they initially start to decrease in size due to flexing of spring 48. Mechanism 120 includes an expansion compartment 124 defined by a cup-like member 126 affixed to wall 40 in any of several known manners, through passages 128, 130 in wall 40 and member 126, and a floating piston or valving member 132 movable in compartment 124 between positions blocking one of the passages and unblocking the other passage. The structure and operation of mechanism 122 is basically the same as mechanism 120 and therefore is not described further.

When isolator 34 is in operation, volumes 44a, 44b are alternately tending to decrease and increase in size in response to rather small torsionals caused by normal engine cylinder power pulses. Hence, a torsional that is currently now, for example, tending to decrease the size of volume 44a and increase the size of volume 44b was preceded by a torsional that had done the opposite. Accordingly, the pressure in chamber 44a is low relative to torque converter pressure surrounding the isolator and valving member 132 is sealingly seated over passage 130 as the current oncoming torsional begins. As volume 44a decreases in size due to the oncoming torsional, the pressure in volume 44a exceeds torque converter pressure, thereby moving valving member 132 to a position seated over passage 128 and allowing the size of volume 44a to increase by the size of compartment 124. An unshown low force spring may be used to bias valving member 132 over passage 130 and the corresponding valving member over the passage to chamber 44b in mechanism 122.

The appended claims are intended to cover the disclosed embodiments of the present invention and modification thereof believed to be within the spirit and scope of the invention.

Claims

1. A torsion isolator (34) including first and second drives (46 and 38, 40) mounted for relative rotation about a common axis (22a); a c-shaped spring (48) having a flexible major arc portion thereof circumscribing the axis and

having first and second circumferentially spaced apart ends (48a, 48b); attachment means (58, 60) for connecting the first and second ends respectively to the first and second drives (46 and 38, 40) a radial distance from the axis (22a); the spring (48) for transmitting torque between the drives and for attenuating torsionals; the spring ends (48a, 48b) circumferentially movable relative to each other in response to changing values of the torque and torsionals; characterized by:

the spring first and second ends (48a, 48b) respectively including first and second brackets (54) rigidly affixed thereto;

pivot means (58, 60) pivotally connecting the first and second brackets (54) respectively to the first and second drives (46 and 38, 40); and

stop means (42e, 54g) operative in response to a predetermined amount of pivotal movement of the brackets (54) to stop further pivotal movement.

2. The isolator of claim 1, wherein:

the spring means (48) is a composite spring formed by a plurality of reinforcing filaments (47) bonded together by a plastic material (49).

3. The isolator of claim 1, further including a dampening mechanism (38, 40, 46, 48) for reducing the rate of flexing of the major arc in response to the relative circumferential movement of the spring ends (48a, 48b).

4. The mechanism of claim 3, wherein:

the dampening mechanism (38, 40, 46, 48) is a fluid dampener mechanism.

5. The isolator of claim 4, wherein:

the spring means (48) is a composite spring formed by a plurality of reinforcing filaments (47) bonded together by a plastic material (49).

6. The isolator of claim 1, wherein:

the pivot means (58, 60) includes a first pin (58) received in an opening in a radially inward portion of the first bracket (54) and in the first drive (46), and a second pin (60) received in an opening in a radially inward portion of the second bracket (54) and in the second drive (38, 40).

7. The isolator of claim 6, wherein:

the stop means (42e, 54g) radially outwardly and a radially inwardly facing surface respectively rigid with one of the drives (46)

and the bracket (54) affixed to the one drive (46) and the surfaces operative to engage in response to the predetermined pivotal movement for stopping the pivotal movement of the bracket relative to the one drive.

8. The isolator of claim 7, wherein:

the spring means (48) is a composite spring formed by a plurality of reinforcing filaments (47) bonded together by a plastic material (49).

9. A torsion isolator (34) including first and second drives (46 and 38, 40) mounted for relative rotation about a common axis (22a); a c-shaped spring (48) having a flexible major arc portion thereof circumscribing the axis and having first and second circumferentially spaced apart ends (48a, 48b); attachment means (58, 60) for connecting the first and second ends respectively to the first and second drives (46 and 38, 40) a radial distance from the axis; the spring (48) for transmitting torque between the drives and for attenuating torsionals; the spring ends (38a, 38b) circumferentially movable relative to each other in response to changing values of the torque and torsionals, thereby flexing the major arc portion and changing concentricity of the spring relative to the axis and thereby changing rotational balance of the isolator (34); characterized by:

an active counterbalance mechanism (54 or 92) including a counterweight (54 or 94) carried by one of the drives and positioning means (58, 60 or 98a) for moving the counterweight to a position countering the changing rotational balance of the isolator in response to the relative circumferential movement of the spring ends (48a, 48b).

10. The isolator of claim 9, wherein:

the positioning means (58, 60 or 98a) includes means for moving the counterweight (54 or 94) radially relative to the axis (22a) in response to the relative circumferential movement of the spring ends (48a, 48b).

11. The isolator of claim 9, further including a dampening mechanism (46, 38, 40, 48) for reducing the rate of flexing of the major arc in response to the relative circumferential movement of the spring ends (48a, 48b).

12. The isolator of claim 9, wherein:

the first drive includes a housing (38, 40) defining an annular chamber (44) having inner and outer radially spaced apart surfaces (42f, 38d) and axially spaced apart surfaces (38b,

40c);

the second drive (46) including a hub (46) having a portion (46e) interior of the chamber;

the spring (48) and a liquid disposed in the chamber (44), the spring having axially oppositely facing surfaces (48c, 48d) in close relation with the chamber axially facing surfaces (38b, 40c) for dividing the chamber into circumferentially inner and outer volumes (44a, 44b) which vary inversely in volume in response to relative rotation of the housing (38, 40) and hub (46) causing the relative circumferential movement of the spring ends (44a, 44b) to create relative liquid pressure in the volumes for opposing the relative rotation.

13. The isolator of claim 9, wherein:

the counterbalance mechanism (92) includes a radially extending guide (96a) affixed to one of the drives (96), a counterweight (94) disposed for radial sliding movement in the guide, and a cam (98a) affixed to the other drive (100) operative to move the counterweight (94) radially in the guide (96a) in response to the relative circumferential movement of the spring ends (48a, 48b).

14. A torsion isolator (34) including a housing (38, 40) and a hub (46) mounted for limited relative rotation about a common axis (22a), the housing including an annular chamber (44) having inner and outer radially spaced apart surfaces (42f, 38d) and axially spaced apart surfaces (38b, 40c); spring means (48) and a liquid disposed in the chamber (44), the spring means (48) having first and second end means (54) respectively connected to a hub portion (46a) interior of the chamber (44) and the housing (38, 40), and the spring means (48) having axially oppositely facing surfaces (48c, 48d) in close relation with the chamber axially facing surfaces (38b, 40c); characterized by:

the spring means (48) being a c-shaped spring means having the first and second end means (54) circumferentially spaced apart, the axially oppositely facing surfaces (48c, 48d) of the c-shaped spring means and surfaces (54b, 54c, 54d) of the first and second end means (54) dividing the annular chamber into circumferentially inner and outer volumes (44a, 44b) which vary inversely in volume in response to relative rotation of the housing (38, 40) and hub (46) causing the end means (54) to move circumferentially toward and away from each other to create relative liquid pressures in the volumes (44a, 44b) for opposing the relative rotation.

15. The isolator of claim 14, wherein:

the first and second end means (54) include first and second brackets (54) rigidly affixed to the spring means (48) and each including a radially outer portion (54d) in sealing relation with the chamber outer surface (38d).

5

16. The isolator of claim 15, wherein:

the hub interior portion (46e) is axially free floating relative to the first bracket (54).

10

17. The isolator of claim 14, disposed in a torque converter housing (28) filled with torque converter oil defining the liquid in the annular chamber, the torque converter housing containing an impeller (26) driven by the torque converter housing (28) and a turbine (32), means (53) drivingly connecting the isolator hub (46) to the turbine (32) and means (35) for selectively drivingly connecting the isolator housing to the torque converter housing (28).
